BEFORE

THE PUBLIC SERVICE COMMISSION OF

SOUTH CAROLINA

LOCKHART POWER COMPANY

Docket No. 2007-33-E

Appendices A through K
to Accompany the
Direct Testimony

of

Paul R. Moul, Managing Consultant
P. Moul & Associates

Concerning

Cost of Equity

APPENDIX A TO DIRECT TESTIMONY OF PAUL R. MOUL

EDUCATIONAL BACKGROUND, BUSINESS EXPERIENCE
AND QUALIFICATIONS

I was awarded a degree of Bachelor of Science in Business Administration by Drexel University in 1971. While at Drexel, I participated in the Cooperative Education Program which included employment, for one year, with American Water Works Service Company, Inc., as an internal auditor, where I was involved in the audits of several operating water companies of the American Water Works System and participated in the preparation of annual reports to regulatory agencies and assisted in other general accounting matters.

Upon graduation from Drexel University, I was employed by American Water Works Service Company, Inc., in the Eastern Regional Treasury Department where my duties included preparation of rate case exhibits for submission to regulatory agencies, as well as responsibility for various treasury functions of the thirteen New England operating subsidiaries.

In 1973, I joined the Municipal Financial Services Department of Betz Environmental Engineers, a consulting engineering firm, where I specialized in financial studies for municipal water and wastewater systems.

In 1974, I joined Associated Utility Services, Inc., now known as AUS Consultants. I held various positions with the Utility Services Group of AUS Consultants, concluding my employment there as a Senior Vice President.

1   In 1994, I formed P. Moul & Associates, an independent financial and regulatory
2   consulting firm. In my capacity as Managing Consultant and for the past twenty-nine years, I
3   have continuously studied the rate of return requirements for cost of service regulated firms. In
4   this regard, I have supervised the preparation of rate of return studies which were employed in
5   connection with my testimony and in the past for other individuals. I have presented direct

1   testimony on the subject of fair rate of return, evaluated rate of return testimony of other

2   witnesses, and presented rebuttal testimony.

3   My studies and prepared direct testimony have been presented before thirty (30) federal,

4   state and municipal regulatory commissions, consisting of: the Federal Energy Regulatory

5   Commission; state public utility commissions in Alabama, Connecticut, Delaware, Florida,

6   Georgia, Hawaii, Illinois, Indiana, Iowa, Kentucky, Maine, Maryland, Massachusetts, Michigan,

7   Minnesota, Missouri, New Hampshire, New Jersey, New York, North Carolina, Oklahoma,

8   Ohio, Pennsylvania, South Carolina, Tennessee, Texas, Virginia, and West Virginia; and the

9   Philadelphia Gas Commission. My testimony has been offered in over 200 rate cases involving

10   electric power, natural gas distribution and transmission, resource recovery, solid waste

11   collection and disposal, telephone, wastewater, and water service utility companies. While my

12   testimony has involved principally fair rate of return and financial matters, I have also testified

13   on capital allocations, capital recovery, cash working capital, income taxes, factoring of accounts

14   receivable, and take-or-pay expense recovery. My testimony has been offered on behalf of

15   municipal and investor-owned public utilities and for the staff of a regulatory commission. I

16   have also testified at an Executive Session of the State of New Jersey Commission of

17   Investigation concerning the BPU regulation of solid waste collection and disposal.

18   I was a co-author of a verified statement submitted to the Interstate Commerce

19   Commission concerning the 1983 Railroad Cost of Capital (Ex Parte No. 452). I was also co-

20   author of comments submitted to the Federal Energy Regulatory Commission regarding the

21   Generic Determination of Rate of Return on Common Equity for Public Utilities in 1985, 1986

22   and 1987 (Docket Nos. RM85-19-000, RM86-12-000, RM87-35-000 and RM88-25-000).

23   Further, I have been the consultant to the New York Chapter of the National Association of

1 Water Companies which represented the water utility group in the Proceeding on Motion of the

2 Commission to Consider Financial Regulatory Policies for New York Utilities (Case 91-M-

3 0509). I have also submitted comments to the Federal Energy Regulatory Commission in its

4 Notice of Proposed Rulemaking (Docket No. RM99-2-000) concerning Regional Transmission

5 Organizations and on behalf of the Edison Electric Institute in its intervention in the case of

6 Southern California Edison Company (Docket No. ER97-2355-000).

7   In late 1978, I arranged for the private placement of bonds on behalf of an investor-

8 owned public utility. I have assisted in the preparation of a report to the Delaware Public Service

9 Commission relative to the operations of the Lincoln and Ellendale Electric Company. I was

10 also engaged by the Delaware P.S.C. to review and report on the proposed financing and

11 disposition of certain assets of Sussex Shores Water Company (P.S.C. Docket Nos. 24-79 and

12 47-79). I was a co-author of a Report on Proposed Mandatory Solid Waste Collection Ordinance

13 prepared for the Board of County Commissioners of Collier County, Florida.

14   I have been a consultant to the Bucks County Water and Sewer Authority concerning

15 rates and charges for wholesale contract service with the City of Philadelphia. My municipal

16 consulting experience also included an assignment for Baltimore County, Maryland, regarding

17 the City/County Water Agreement for Metropolitan District customers (Circuit Court for

18 Baltimore County in Case 34/153/87-CSP-2636).

19   I am a member of the Society of Utility and Regulatory Financial Analysis (formerly the

20 National Society of Rate of Return Analysts) and have attended several Financial Forums

21 sponsored by the Society. I attended the first National Regulatory Conference at the Marshall-

22 Wythe School of Law, College of William and Mary. I also attended an Executive Seminar

23 sponsored by the Colgate Darden Graduate Business School of the University of Virginia

1   concerning Regulated Utility Cost of Equity and the Capital Asset Pricing Model. In October

2   1984, I attended a Standard & Poor's Seminar on the Approach to Municipal Utility Ratings, and

3   in May 1985, I attended an S&P Seminar on Telecommunications Ratings.

4   My lecture and speaking engagements include:

Date	Occasion	Sponsor
April 2006	Thirty-eighth Financial Forum	Society of Utility & Regulatory Financial Analysts
April 2001	Thirty-third Financial Forum	Society of Utility & Regulatory Financial Analysts
December 2000	Pennsylvania Public Utility Law Conference: Non-traditional Players in the Water Industry	Pennsylvania Bar Institute
July 2000	EEI Member Workshop Developing Incentives Rates: Application and Problems	Edison Electric Institute
February 2000	The Sixth Annual FERC Briefing	Exnet and Bruder, Gentile & Marcoux, LLP
March 1994	Seventh Annual Proceeding	Electric Utility Business Environment Conf.
May 1993	Financial School	New England Gas Assoc.
April 1993	Twenty-Fifth Financial Forum	National Society of Rate of Return Analysts
June 1992	Rate and Charges Subcommittee Annual Conference	American Water Works Association
May 1992	Rates School	New England Gas Assoc.
October 1989	Seventeenth Annual Eastern Utility Rate Seminar	Water Committee of the National Association of Regulatory Utility Commissioners Florida Public Service Commission and University of Utah
October 1988	Sixteenth Annual Eastern Utility Rate Seminar	Water Committee of the National Association of Regulatory Utility Commissioners, Florida Public Service Commission and University of Utah

1	May 1988	Twentieth Financial	National Society of

31		Regulation	

1   **RATESETTING PRINCIPLES**

2   Under traditional cost of service regulation, an agency engaged in ratesetting, such as the

3   Commission, serves as a substitute for competition. In setting rates, a regulatory agency must

4   carefully consider the public's interest in reasonably priced, as well as safe and reliable, service.

5   The level of rates must also provide an opportunity to earn a rate of return for the public utility

6   and its investors that is commensurate with the risk to which the invested capital is exposed so

7   that the public utility has access to the capital required to meet its service responsibilities to its

8   customers. Without an opportunity to earn a fair rate of return, a public utility will be unable to

9   attract sufficient capital required to meet its responsibilities over time.

10   It is important to remember that regulated firms must compete for capital in a global

11   market with non-regulated firms, as well as municipal, state and federal governments.

12   Traditionally, a public utility has been responsible for providing a particular type of service to its

13   customers within a specific market area. Although this relationship with its customers has been

14   changing, it remains quite different from a non-regulated firm which is free to enter and exit

15   competitive markets in accordance with available business opportunities.

16   As established by the landmark Bluefield and Hope cases,[1] several tests must be satisfied

17   to demonstrate the fairness or reasonableness of the rate of return. These tests include a

18   determination of whether the rate of return is (i) similar to that of other financially sound

19   businesses having similar or comparable risks, (ii) sufficient to ensure confidence in the financial

20   integrity of the public utility, and (iii) adequate to maintain and support the credit of the utility,

21   thereby enabling it to attract, on a reasonable cost basis, the funds necessary to satisfy its capital

---

[1]   Bluefield Water Works & Improvement Co. v. P.S.C. of West Virginia, 262 U.S. 679 (1923) and F.P.C. v. Hope Natural Gas Co., 320 U.S. 591 (1944).

1   requirements so that it can meet the obligation to provide adequate and reliable service to the

2   public.

3   A fair rate of return must not only provide the utility with the ability to attract new

4   capital, it must also be fair to existing investors. An appropriate rate of return which may have

5   been reasonable at one point in time may become too high or too low at a subsequent point in

6   time, based upon changing business risks, economic conditions and alternative investment

7   opportunities. When applying the standards of a fair rate of return, it must be recognized that the

8   end result must provide for the payment of interest on the company's debt, the payment of

9   dividends on the company's stock, the recovery of costs associated with securing capital, the

10   maintenance of reasonable credit quality for the company, and support of the company's financial

11   condition, which today would include those measures of financial performance in the areas of

12   interest coverage and adequate cash flow derived from a reasonable level of earnings.

1   **<u>EVALUATION OF RISK</u>**

2   The rate of return required by investors is directly linked to the perceived level of risk.

3 The greater the risk of an investment, the higher is the required rate of return necessary to

4 compensate for that risk all else being equal. Because investors will seek the highest rate of

5 return available, considering the risk involved, the rate of return must at least equal the investor-

6 required, market-determined cost of capital if public utilities are to attract the necessary

7 investment capital on reasonable terms.

8   In the measurement of the cost of capital, it is necessary to assess the risk of a firm. The

9 level of risk for a firm is often defined as the uncertainty of achieving expected performance, and

10 is sometimes viewed as a probability distribution of possible outcomes. Hence, if the uncertainty

11 of achieving an expected outcome is high, the risk is also high. As a consequence, high risk

12 firms must offer investors higher returns than low risk firms which pay less to attract capital

13 from investors. This is because the level of uncertainty, or risk of not realizing expected returns,

14 establishes the compensation required by investors in the capital markets. Of course, the risk of

15 a firm must also be considered in the context of its ability to actually experience adequate

16 earnings which conform with a fair rate of return. Thus, if there is a high probability that a firm

17 will not perform well due to fundamentally poor market conditions, investors will demand a

18 higher return.

19   The investment risk of a firm is comprised of its business risk and financial risk.

20 Business risk is all risk other than financial risk, and is sometimes defined as the staying power

21 of the market demand for a firm's product or service and the resulting inherent uncertainty of

22 realizing expected pre-tax returns on the firm's assets. Business risk encompasses all operating

23 factors, e.g., productivity, competition, management ability, etc. that bear upon the expected pre-

1   tax operating income attributed to the fundamental nature of a firm's business. Financial risk

2   results from a firm's use of borrowed funds (or similar sources of capital with fixed payments) in

3   its capital structure, i.e., financial leverage. Thus, if a firm did not employ financial leverage by

4   borrowing any capital, its investment risk would be represented by its business risk.

5   It is important to note that in evaluating the risk of regulated companies, financial

6   leverage cannot be considered in the same context as it is for non-regulated companies.

7   Financial leverage has a different meaning for regulated firms than for non-regulated companies.

8   For regulated public utilities, the cost of service formula gives the benefits of financial leverage

9   to consumers in the form of lower revenue requirements. For non-regulated companies, all

10   benefits of financial leverage are retained by the common stockholder. Although retaining none

11   of the benefits, regulated firms bear the risk of financial leverage. Therefore, a regulated firm's

12   rate of return on common equity must recognize the greater financial risk shown by the higher

13   leverage typically employed by public utilities.

14   Although no single index or group of indices can precisely quantify the relative

15   investment risk of a firm, financial analysts use a variety of indicators to assess that risk. For

16   example, the creditworthiness of a firm is revealed by its bond ratings. If the stock is traded, the

17   price-earnings multiple, dividend yield, and beta coefficients (a statistical measure of a stock's

18   relative volatility to the rest of the market) provide some gauge of overall risk. Other indicators,

19   which are reflective of business risk, include the variability of the rate of return on equity, which

20   is indicative of the uncertainty of actually achieving the expected earnings; operating ratios (the

21   percentage of revenues consumed by operating expenses, depreciation, and taxes other than

22   income tax), which are indicative of profitability; the quality of earnings, which considers the

23   degree to which earnings are the product of accounting principles or cost deferrals; and the level

1   of internally generated funds. Similarly, the proportion of senior capital in a company's

2   capitalization is the measure of financial risk which is often analyzed in the context of the equity

3   ratio (i.e., the complement of the debt ratio).

1 ## COST OF EQUITY--GENERAL APPROACH

2   Through a fundamental financial analysis, the relative risk of a firm must be established

3 prior to the determination of its cost of equity. Any rate of return recommendation which lacks

4 such a basis will inevitably fail to provide a utility with a fair rate of return except by

5 coincidence. With a fundamental risk analysis as a foundation, standard financial models can be

6 employed by using informed judgment. The methods which have been employed to measure the

7 cost of equity include: the Discounted Cash Flow ("DCF") model, the Risk Premium ("RP")

8 approach, the Capital Asset Pricing Model ("CAPM") and the Comparable Earnings ("CE")

9 approach.

10   The traditional DCF model, while useful in providing some insight into the cost of equity,

11 is not an approach that should be used exclusively. The divergence of stock prices from

12 company-specific fundamentals can provide a misleading cost of equity calculation. As reported

13 in The Wall Street Journal on June 6, 1991, a statistical study published by Goldman Sachs

14 indicated that only 35% of stock price growth in the 1980's could be attributed to earnings and

15 interest rates. Further, 38% of the rise in stock prices during the 1980's was attributed to

16 unknown factors. The Goldman Sachs study highlights the serious limitations of a model, such

17 as DCF, which is founded upon identification of specific variables to explain stock price growth.

18 That is to say, when stock price growth exceeds growth in a company's earnings per share,

19 models such as DCF will misspecify investor expected returns which are comprised of capital

20 gains, as well as dividend receipts. As such, a combination of methods should be used to

21 measure the cost of equity.

1   The Risk Premium analysis is founded upon the prospective cost of long-term debt, i.e.,

2   the yield that the public utility must offer to raise long-term debt capital directly from investors.

3   To that yield must be added a risk premium in recognition of the greater risk of common equity

4   over debt. This additional risk is, of course, attributable to the fact that the payment of interest

5   and principal to creditors has priority over the payment of dividends and return of capital to

6   equity investors. Hence, equity investors require a higher rate of return than the yield on long-

7   term corporate bonds.

8   The CAPM is a model not unlike the traditional Risk Premium. The CAPM employs the

9   yield on a risk-free interest-bearing obligation plus a premium as compensation for risk. Aside

10   from the reliance on the risk-free rate of return, the CAPM gives specific quantification to

11   systematic (or market) risk as measured by beta.

12   The Comparable Earnings approach measures the returns expected/experienced by other

13   non-regulated firms and has been used extensively in rate of return analysis for over a half

14   century. However, its popularity diminished in the 1970s and 1980s with the popularization of

15   market-based models. Recently, there has been renewed interest in this approach. Indeed, the

16   financial community has expressed the view that the regulatory process must consider the returns

17   which are being achieved in the non-regulated sector so that public utilities can compete

18   effectively in the capital markets. Indeed, with additional competition being introduced

19   throughout the traditionally regulated public utility industry, returns expected to be realized by

20   non-regulated firms have become increasing relevant in the ratesetting process. The Comparable

21   Earnings approach considers directly those requirements and it fits the established standards for a

1   fair rate of return set forth in the <u>Bluefield</u> decision. The <u>Bluefield</u> decisions require that a fair

2   return for a utility must be equal to that earned by firms of comparable risk.

1   **DISCOUNTED CASH FLOW ANALYSIS**

2   Discounted Cash Flow ("DCF") theory seeks to explain the value of an economic or

3 financial asset as the present value of future expected cash flows discounted at the appropriate

4 risk-adjusted rate of return. Thus, if $100 is to be received in a single payment 10 years

5 subsequent to the acquisition of an asset, and the appropriate risk-related interest rate is 8%, the

6 present value of the asset would be $46.32 (Value = $100 ÷ $(1.08)^{10}$) arising from the discounted

7 future cash flow. Conversely, knowing the present $46.32 price of an asset (where price =

8 value), the $100 future expected cash flow to be received 10 years hence shows an 8% <u>annual</u>

9 rate of return implicit in the price and future cash flows expected to be received.

10   In its simplest form, the DCF theory considers the number of years from which the cash

11 flow will be derived and the annual compound interest rate which reflects the risk or uncertainty

12 associated with the cash flows. It is appropriate to reiterate that the dollar values to be

13 discounted are future cash flows.

14   DCF theory is flexible and can be used to estimate value (or price) or the annual required

15 rate of return under a wide variety of conditions. The theory underlying the DCF methodology

16 can be easily illustrated by utilizing the investment horizon associated with a preferred stock not

17 having an annual sinking fund provision. In this case, the investment horizon is infinite, which

18 reflects the perpetuity of a preferred stock. If P represents price, Kp is the required rate of return

19 on a preferred stock, and D is the annual dividend (P and D with time subscripts), the value of a

20 preferred share is equal to the present value of the dividends to be received in the future

21 discounted at the appropriate risk-adjusted interest rate, Kp. In this circumstance:

22

1

$$P_0 = \frac{D_1}{(1+Kp)} + \frac{D_2}{(1+Kp)^2} + \frac{D_3}{(1+Kp)^3} + \ldots + \frac{D_n}{(1+Kp)^n}$$

2 If $D_1 = D_2 = D_3 = \ldots D_n$ as is the case for preferred stock, and n approaches infinity, as is the

3 case for non-callable preferred stock without a sinking fund, then this equation reduces to:

4

$$P_0 = \frac{D_1}{Kp}$$

5 This equation can be used to solve for the annual rate of return on a preferred stock when the

6 current price and subsequent annual dividends are known. For example, with $D_1 = \$1.00$, and P_0

7 $= \$10$, then $Kp = \$1.00 \div \$10$, or 10%.

8   The dividend discount equation, first shown, is the generic DCF valuation model for all

9 equities, both preferred and common. While preferred stock generally pays a constant dividend,

10 permitting the simplification subsequently noted, common stock dividends are not constant.

11 Therefore, absent some other simplifying condition, it is necessary to rely upon the generic form

12 of the DCF. If, however, it is assumed that D_1, D_2, D_3, $\ldots D_n$ are systematically related to one

13 another by a constant growth rate *(g)*, so that $D_0 (1 + g) = D_1$, $D_1 (1 + g) = D_2$, $D_2 (1 + g) = D_3$

14 and so on approaching infinity, and if *Ks* (the required rate of return on a common stock) is

15 greater than *g*, then the DCF equation can be reduced to:

$$P_0 = \frac{D_1}{Ks - g} \quad or \quad P_0 = \frac{D_0 (1+g)}{Ks - g}$$

E-2

1   which is the periodic form of the "Gordon" model.[1] Proof of the DCF equation is found in all

2   modern basic finance textbooks. This DCF equation can be easily solved as:

$$Ks = \frac{D_0\,(1+g)}{P_0} + g$$

3   which is the periodic form of the Gordon Model commonly applied in estimating equity rates of

4   return in rate cases. When used for this purpose, Ks is the annual rate of return on common

5   equity demanded by investors to induce them to hold a firm's common stock. Therefore, the

6   variables D_0, P_0 and g must be estimated in the context of the market for equities, so that the rate

7   of return, which a public utility is permitted the opportunity to earn, has meaning and reflects the

8   investor-required cost rate.

9   Application of the Gordon model with market derived variables is straightforward. For

10   example, using the most recent prior annualized dividend (D_0) of $0.80, the current price (P_0) of

11    $10.00, and the investor expected dividend growth rate (g) of 5%, the solution of the DCF

12   formula provides a 13.4% rate of return. The dividend yield component in this instance is 8.4%,

13   and the capital gain component is 5%, which together represent the total 13.4% annual rate of

14   return required by investors. The capital gain component of the total return may be calculated

15   with two adjacent future year prices. For example, in the eleventh year of the holding period, the

16   price per share would be $17.10 as compared with the price per share of $16.29 in the tenth year

17   which demonstrates the 5% annual capital gain yield.

---

[1]   Although the popular application of the DCF model is often attributed to the work of Myron J. Gordon in
the mid-1950's, J. B. Williams exposited the DCF model in its present form nearly two decades earlier.

1   Some DCF devotees believe that it is more appropriate to estimate the required return on

2   equity with a model which permits the use of multiple growth rates. This may be a plausible

3   approach to DCF, where investors expect different dividend growth rates in the near term and

4   long run. If two growth rates, one near term and one long-run, are to be used in the context of a

5   price (P_0) of $10.00, a dividend (D_0) of $0.80, a near-term growth rate of 5.5%, and a long-run

6   expected growth rate of 5.0% beginning at year 6, the required rate of return is 13.57% solved

7   with a computer by iteration.

8   **Use of DCF in Ratesetting**

9   The DCF method can provide a misleading measure of the cost of equity in the

10   ratesetting process when stock prices diverge from book values by a meaningful margin. When

11   the difference between share values and book values is significant, the results from the DCF can

12   result in a misspecified cost of equity when those results are applied to book value. This is

13   because investor expected returns, as described by the DCF model, are related to the market

14   value of common stock. This discrepancy is shown by the following example. If it is assumed,

15   hypothetically, that investors require a 12.5% return on their common stock investment value

16   (i.e., the market price per share) when share values represent 150% of book value, investors

17   would require a total annual return of $1.50 per share on a $12.00 market value to realize their

18   expectations. If, however, this 12.5% market-determined cost rate is applied to an original cost

19   rate base which is equivalent to the book value of common stock of $8.00 per share, the utility's

20   actual earnings per share would be only $1.00. This would result in a $.50 per share earnings

21   shortfall which would deny the utility the ability to satisfy investor expectations.

1   As a consequence, a utility could not withstand these DCF results applied in a rate case

2   and also sustain its financial integrity. This is because $1.00 of earnings per share and a 75%

3   dividend payout ratio would provide earnings retention growth of just 3.125% (i.e., $1.00 x .75 =

4    $0.75, and $1.00 - $0.75 = $0.25 ÷ $8.00 = 3.125%). In this example, the earnings retention

5   growth rate plus the 6.25% dividend yield ($0.75 ÷ $12.00) would equal 9.375% (6.25% +

6   3.125%) as indicated by the DCF model. This DCF result is the same as the utility's rate of

7   dividend payments on its book value (i.e., $0.75 ÷ $8.00 = 9.375%). This situation provides the

8   utility with no earnings cushion for its dividend payment because the DCF result equals the

9   dividend rate on book value (i.e., both rates are 9.375% in the example). Moreover, if the price

10   employed in my example were higher than 150% of book value, a "negative" earnings cushion

11   would develop and cause the need for a dividend reduction because the DCF result would be less

12   than the dividend rate on book value. For these reasons, the usefulness of the DCF method

13   significantly diminishes as market prices and book values diverge.

14   Further, there is no reason to expect that investors would necessarily value utility stocks

15   equal to their book value. In fact, it is rare that utility stocks trade at book value. Moreover,

16   high market-to-book ratios may be reflective of general market sentiment. Were regulators to

17   use the results of a DCF model, that fails to produce the required return when applied to an

18   original cost rate base, they would penalize a company with high market-to-book ratios. This

19   clearly would penalize a regulated firm and its investors that purchased the stock at its current

20   price. When investor expectations are not fulfilled, the market price per share will decline and a

21   new, different equity cost rate would be indicated from the lower price per share. This condition

22   suggests that the current price would be subject to disequilibrium and would not allow a

1   reasonable calculation of the cost of equity.   This situation would also create a serious

2   disincentive for management initiative and efficiency. Within that framework, a perverse set of

3   goals and rewards would result, i.e., a high authorized rate of return in a rate case would be the

4   reward for poor financial performance, while low rates of return would be the reward for good

5   financial performance. As such, the DCF results should not be used alone to determine the cost

6   of equity, but should be used along with other complementary methods.

7   **Dividend Yield**

8   The historical annual dividend yield for the Electric Group is shown on Schedule 2. The

9   2001-2005 five-year average dividend yield was 4.5% for the Electric Group. The monthly

10   dividend yields for the past twelve months are shown graphically on Schedule 4. These dividend

11   yields reflect an adjustment to the month-end closing prices to remove the pro rata accumulation

12   of the quarterly dividend amount since the last ex-dividend date.

13   The ex-dividend date usually occurs two business days before the record date of the

14   dividend (i.e., the date by which a shareholder must own the shares to be entitled to the dividend

15   payment--usually about two to three weeks prior to the actual payment). During a quarter (here

16   defined as 91 days), the price of a stock moves up ratably by the dividend amount as the ex-

17   dividend date approaches. The stock's price then falls by the amount of the dividend on the ex-

18   dividend date. Therefore, it is necessary to calculate the fraction of the quarterly dividend since

19   the time of the last ex-dividend date and to remove that amount from the price. This adjustment

20   reflects normal recurring pricing of stocks in the market, and establishes a price which will

21   reflect the true yield on a stock.

1   A six-month average dividend yield has been used to recognize the prospective

2   orientation of the ratesetting process as explained in the direct testimony. For the purpose of a

3   DCF calculation, the average dividend yields must be adjusted to reflect the prospective nature

4   of the dividend payments, i.e., the higher expected dividends for the future rather than the recent

5   dividend payment annualized. An adjustment to the dividend yield component, when computed

6   with annualized dividends, is required based upon investor expectation of quarterly dividend

7   increases.

8   The procedure to adjust the average dividend yield for the expectation of a dividend

9   increase during the initial investment period will be at a rate of one-half the growth component,

10   developed below. The DCF equation, showing the quarterly dividend payments as D_0, may be

11   stated in this fashion:

$$K = \frac{D_0\,(1+g\,)^0 + D_0\,(1+g\,)^0 + D_0\,(1+g\,)^1 + D_0\,(1+g\,)^1}{P_0} + g$$

12   The adjustment factor, based upon one-half the expected growth rate developed in my direct

13   testimony, will be 3.125% (6.25% x .5) for the Electric Group, which assumes that two dividend

14   payments will be at the expected higher rate during the initial investment period. Using the six-

15   month average dividend yield as a base, the prospective (forward) dividend yield would be

16   4.38% (4.25% x 1.03125) for the Electric Group.

17   Another DCF model that reflects the discrete growth in the quarterly dividend (D_0) is as

18   follows:

$$K = \frac{D_0 (1 + g)^{.25} + D_0 (1 + g)^{.50} + D_0 (1 + g)^{.75} + D_0 (1 + g)^{1.00}}{P_0} + g$$

1 This procedure confirms the reasonableness of the forward dividend yield previously calculated.

2 The quarterly discrete adjustment provides a dividend yield of 4.41% (4.25% x 1.03877) for the

3 Electric Group. The use of an adjustment is required for the periodic form of the DCF in order to

4 properly recognize that dividends grow on a discrete basis.

5   In either of the preceding DCF dividend yield adjustments, there is no recognition for the

6 compound returns attributed to the quarterly dividend payments. Investors have the opportunity

7 to reinvest quarterly dividend receipts. Recognizing the compounding of the periodic quarterly

8 dividend payments (D_0), results in a third DCF formulation:

$$k = \left[\left(1 + \frac{D_0}{P_0} \right)^4 - 1 \right] + g$$

9 This DCF equation provides no further recognition of growth in the quarterly dividend.

10 Combining discrete quarterly dividend growth with quarterly compounding would provide the

$$k = \left[\left(1 + \frac{D_0 (1 + g)^{.25}}{P_0} \right)^4 - 1 \right] + g$$

11 following DCF formulation, stating the quarterly dividend payments (D_0):

1   A compounding of the quarterly dividend yield provides another procedure to recognize the

2   necessity for an adjusted dividend yield. The unadjusted average quarterly dividend yield was

3   1.062500% (4.25% ÷ 4) for the Electric Group. The compound dividend yield would be 4.39%

4   (1.010787^4-1) for the Electric Group, recognizing quarterly dividend payments in a forward-

5   looking manner. These dividend yields conform with investors' expectations in the context of

6   reinvestment of their cash dividend.

7   For the Electric Group, a 4.39% forward-looking dividend yield is the average (4.38% +

8   4.41% + 4.39% = 13.18% ÷ 3) of the adjusted dividend yield using the form $D_0/P_0\ (1+.5g)$, the

9   dividend yield recognizing discrete quarterly growth, and the quarterly compound dividend yield

10   with discrete quarterly growth.

11   <div align="center">**Growth Rate**</div>

12   If viewed in its infinite form, the DCF model is represented by the discounted value of an

13   endless stream of growing dividends. It would, however, require 100 years of future dividend

14   payments so that the discounted value of those payments would equate to the present price so

15   that the discount rate and the rate of return shown by the simplified Gordon form of the DCF

16   model would be about the same. A century of dividend receipts represents an unrealistic

17   investment horizon from almost any perspective. Because stocks are not held by investors

18   forever, the growth in the share value (i.e., capital appreciation, or capital gains yield) is most

19   relevant to investors' total return expectations. Hence, investor expected returns in the equity

20   market are provided by capital appreciation of the investment as well as receipt of dividends. As

21   such, the sale price of a stock can be viewed as a liquidating dividend which can be discounted

1   along with the annual dividend receipts during the investment holding period to arrive at the

2   investor expected return.

3   In its constant growth form, the DCF assumes that with a constant return on book

4   common equity and constant dividend payout ratio, a firm's earnings per share, dividends per

5   share and book value per share will grow at the same constant rate, absent any external financing

6   by a firm. Because these constant growth assumptions do not actually prevail in the capital

7   markets, the capital appreciation potential of an equity investment is best measured by the

8   expected growth in earnings per share. Since the traditional form of the DCF assumes no change

9   in the price-earnings multiple, the value of a firm's equity will grow at the same rate as earnings

10   per share. Hence, the capital gains yield is best measured by earnings per share growth using

11   company-specific variables.

12   Investors consider both historical and projected data in the context of the expected

13   growth rate for a firm. An investor can compute historical growth rates using compound growth

14   rates or growth rate trend lines. Otherwise, an investor can rely upon published growth rates as

15   provided in widely-circulated, influential publications. However, a traditional constant growth

16   DCF analysis that is limited to such inputs suffers from the assumption of no change in the price-

17   earnings multiple, i.e., that the value of a firm's equity will grow at the same rate as earnings.

18   Some of the factors which actually contribute to investors' expectations of earnings growth and

19   which should be considered in assessing those expectations, are: (i) the earnings rate on existing

20   equity, (ii) the portion of earnings not paid out in dividends, (iii) sales of additional common

21   equity, (iv) reacquisition of common stock previously issued, (v) changes in financial leverage,

22   (vi) acquisitions of new business opportunities, (vii) profitable liquidation of assets, and (viii)

1   repositioning of existing assets.   The realities of the equity market regarding total return

2   expectations, however, also reflect factors other than these inputs.   Therefore, the DCF model

3   contains overly restrictive limitations when the growth component is stated in terms of earnings

4   per share (the basis for the capital gains yield) or dividends per share (the basis for the infinite

5   dividend discount model).   In these situations, there is inadequate recognition of the capital gains

6   yields arising from stock price growth which could exceed earnings or dividends growth.

7   To assess the growth component of the DCF, analysts' projections of future growth

8   influence investor expectations as explained above.   One influential publication is The Value

9   Line Investment Survey which contains estimated future projections of growth.   The Value Line

10   Investment Survey provides growth estimates which are stated within a common economic

11   environment for the purpose of measuring relative growth potential.   The basis for these

12   projections is the Value Line 3 to 5 year hypothetical economy.   The Value Line hypothetical

13   economic environment is represented by components and subcomponents of the National Income

14   Accounts which reflect in the aggregate assumptions concerning the unemployment rate,

15   manpower productivity, price inflation, corporate income tax rate, high-grade corporate bond

16   interest rates, and Fed policies.   Individual estimates begin with the correlation of sales, earnings

17   and dividends of a company to appropriate components or subcomponents of the future National

18   Income Accounts.   These calculations provide a consistent basis for the published forecasts.

19   Value Line's evaluation of a specific company's future prospects are considered in the context of

20   specific operating characteristics that influence the published projections.   Of particular

21   importance for regulated firms, Value Line considers the regulatory quality, rates of return

22   recently authorized, the historic ability of the firm to actually experience the authorized rates of

1   return, the firm's budgeted capital spending, the firm's financing forecast, and the dividend

2   payout ratio. The wide circulation of this source and frequent reference to Value Line in

3   financial circles indicate that this publication has an influence on investor judgment with regard

4   to expectations for the future.

5   There are other sources of earnings growth forecasts. One of these sources is the

6   Institutional Brokers Estimate System ("IBES"). The IBES service provides data on consensus

7   earnings per share forecasts and five-year earnings growth rate estimates. The publisher of IBES

8   has been purchased by Thomson/First Call. The IBES forecasts have been integrated into the

9   First Call consensus growth forecasts. The earnings estimates are obtained from financial

10   analysts at brokerage research departments and from institutions whose securities analysts are

11   projecting earnings for companies in the First Call universe of companies. Other services that

12   tabulate earnings forecasts and publish them are Zacks Investment Research and Market Guide

13   (which is provided over the Internet by Reuters). As with the IBES/First Call forecasts, Zacks

14   and Reuters/Market Guide provide consensus forecasts collected from analysts for most

15   publically traded companies.

16   In each of these publications, forecasts of earnings per share for the current and

17   subsequent year receive prominent coverage. That is to say, IBES/First Call, Zacks,

18   Reuters/Market Guide, and Value Line show estimates of current-year earnings and projections

19   for the next year. While the DCF model typically focusses upon long-run estimates of growth,

20   stock prices are clearly influenced by current and near-term earnings prospects. Therefore, the

21   near-term earnings per share growth rates should also be factored into a growth rate

22   determination.

1   Although forecasts of future performance are investor influencing[2], equity investors may

2   also rely upon the observations of past performance. Investors' expectations of future growth

3   rates may be determined, in part, by an analysis of historical growth rates. It is apparent that any

4   serious investor would advise himself/herself of historical performance prior to taking an

5   investment position in a firm. Earnings per share and dividends per share represent the principal

6   financial variables which influence investor growth expectations.

7   Other financial variables are sometimes considered in rate case proceedings. For

8   example, a company's internal growth rate, derived from the return rate on book common equity

9   and the related retention ratio, is sometimes considered. This growth rate measure is represented

10   by the Value Line forecast "*BxR*" shown on Schedule 6 Internal growth rates are often used as a

11   proxy for book value growth. Unfortunately, this measure of growth is often not reflective of

12   investor-expected growth. This is especially important when there is an indication of a

13   prospective change in dividend payout ratio, earned return on book common equity, change in

14   market-to-book ratios or other fundamental changes in the character of the business.

15   Nevertheless, I have also shown the historical and projected growth rates in book value per share

16   and internal growth rates.

---

[2]   As shown in a National Bureau of Economic Research monograph by John G. Cragg and Burton G. Malkiel, <u>Expectations and the Structure of Share Prices</u>, University of Chicago Press 1982.

1 **FLOTATION COST ADJUSTMENT**

2   The rate of return on common equity must be high enough to avoid dilution when

3 additional common equity is issued. In this regard, the rate of return on book common equity for

4 public utilities requires recognition of specific factors other than just the market-determined cost

5 of equity. A market price of common stock above book value is necessary to attract future capital

6 on reasonable terms in competition with other seekers of equity capital. Non-regulated

7 companies traditionally have experienced common stock prices consistently above book value.

8 For a public utility to be competitive in the capital markets, similar recognition should be

9 provided, given the understated value of net plant investment which is represented by historical

10 costs much lower than current cost. Moreover, the market value of a public utility stock must be

11 above book value to provide recognition of market pressure, issuance and selling expenses which

12 reduce the net proceeds realized from the sale of new shares of common stock. A market price

13 of stock above book value will maintain the financial integrity of shares previously issued and is

14 necessary to avoid dilution when new shares are offered.

15   The rate of return on common equity should provide for the underwriting discount and

16 company issuance expenses associated with the sale of new common stock. It is the net

17 proceeds, after payment of these costs that are available to the company, because the issuance

18 costs are paid from the initial offering price to the public. Market pressure occurs when the news

19 of an impending issue of new common shares impacts the pre-offering price of stock. The stock

20 price often declines because of the prospect of an increase in the supply of shares. The difficulty

21 encountered in measuring market pressure relates to the time frame considered, general market

22 conditions, and management action during the offering period. An indication of negative market

1   pressure could be the product of the techniques employed to measure pressure and not the

2   prospect of an additional supply of shares related to the new issue.

3   Even in the situation where a company will not issue common stock during the near term,

4   the flotation cost adjustment factor should be applied to the common equity cost rate. A public

5   utility must be in a competitive capital attraction posture at all times. To deny recognition of a

6   market value of equity above book value would be discriminatory when other comparable

7   companies receive an allowance in this regard. Moreover, to reduce the return rate on common

8   equity by failing to recognize this factor would likewise result in a company being less

9   competitive in the bond market, because a lower resulting overall rate of return would provide

10   less competitive fixed-charge coverage. It cannot be said that a public utility's stock price

11   already considers an allowance for flotation costs. This is because investors in either fixed-

12   income bonds or common stocks seek their required rate of return by reference to alternative

13   investment opportunities, and are not concerned with the issuance costs incurred by a firm

14   borrowing long-term debt or issuing common equity.

15   Historical data concerning issuance and selling expenses (excluding market pressure) is

16   shown on Schedule 7. To adjust for the cost of raising new common equity capital, the rate of

17   return on common equity should recognize an appropriate multiple in order to allow for a market

18   price of stock above book value. This would provide recognition for flotation costs, which are

19   shown to be 3.3% for public offerings of common stocks by electric companies from 2001 to

20   2005. Because these costs are not recovered elsewhere, they must be recognized in the rate of

21   return. Since I apply the flotation cost to the entire cost of equity, I have only used a

22   modification factor of 1.02 which is applied to the unadjusted DCF-measure of the cost of equity

1   to cover issuance expense. If the modification factor were applied to only a portion of the cost of

2   equity, such as just the dividend yield, then a higher factor would be necessary.

1 ## INTEREST RATES

2   Interest rates can be viewed in their traditional nominal terms (i.e., the stated rate of

3 interest) and in real terms (i.e., the stated rate of interest less the expected rate of inflation).

4 Absent consideration of inflation, the real rate of interest is determined generally by supply

5 factors which are influenced by investors willingness to forego current consumption (i.e., to

6 save) and demand factors that are influenced by the opportunities to derive income from

7 productive investments. Added to the real rate of interest is compensation required by investors

8 for the inflationary impact of the declining purchasing power of their income received in the

9 future. While interest rates are clearly influenced by the changing annual rate of inflation, it is

10 important to note that the expected rate of inflation that is reflected in current interest rates may

11 be quite different than the prevailing rate of inflation.

12   Rates of interest also vary by the type of interest bearing instrument. Investors require

13 compensation for the risk associated with the term of the investment and the risk of default. The

14 risk associated with the term of the investment is usually shown by the yield curve, i.e., the

15 difference in rates across maturities. The typical structure is represented by a positive yield

16 curve which provides progressively higher interest rates as the maturities are lengthened. Flat

17 (i.e., relatively level rates across maturities) or inverted (i.e., higher short-term rates than long-

18 term rates) yield curves occur less frequently.

19   The risk of default is typically associated with the creditworthiness of the borrower.

20 Differences in interest rates can be traced to the credit quality ratings assigned by the bond rating

21 agencies, such as Moody's Investors Service, Inc. and Standard & Poor's Corporation.

22 Obligations of the United States Treasury are usually considered to be free of default risk, and

23 hence reflect only the real rate of interest, compensation for expected inflation, and maturity risk.

1   The Treasury has been issuing inflation-indexed notes which automatically provide

2   compensation to investors for future inflation, thereby providing a lower current yield on these

3   issues.

4   **Interest Rate Environment**

5   Federal Reserve Board ("Fed") policy actions which impact directly short-term interest

6   rates also substantially affect investor sentiment in long-term fixed-income securities markets. In

7   this regard, the Fed has often pursued policies designed to build investor confidence in the fixed-

8   income securities market. Formative Fed policy has had a long history, as exemplified by the

9   historic 1951 Treasury-Federal Reserve Accord, and more recently, deregulation within the

10   financial system which increased the level and volatility of interest rates. The Fed has indicated

11   that it will follow a monetary policy designed to promote non-inflationary economic growth.

12   As background to the recent levels of interest rates, history shows that the Open Market

13   Committee of the Federal Reserve board ("FOMC") began a series of moves toward lower short-

14   term interest rates in mid-1990 -- at the outset of the previous recession. Monetary policy was

15   influenced at that time by (i) steps taken to reduce the federal budget deficit, (ii) slowing

16   economic growth, (iii) rising unemployment, and (iv) measures intended to avoid a credit crunch.

17   Thereafter, the Federal government initiated several bold proposals to deal with future

18   borrowings by the Treasury. With lower expected federal budget deficits and reduced Treasury

19   borrowings, together with limitations on the supply of new 30-year Treasury bonds, long-term

20   interest rates declined to a twenty-year low, reaching a trough of 5.78% in October 1993.

21   On February 4, 1994, the FOMC began a series of increases in the Fed Funds rate (i.e.,

22   the interest rate on excess overnight bank reserves). The initial increase represented the first rise

23   in short-term interest rates in five years. The series of seven increases doubled the Fed Funds

1   rate to 6%. The increases in short-term interest rates also caused long-term rates to move up,

2   continuing a trend which began in the fourth quarter of 1993. The cyclical peak in long-term

3   interest rates was reached on November 7 and 14, 1994 when 30-year Treasury bonds attained an

4   8.16% yield. Thereafter, long-term Treasury bond yields generally declined.

5   Beginning in mid-February 1996, long-term interest rates moved upward from their

6   previous lows. After initially reaching a level of 6.75% on March 15, 1996, long-term interest

7   rates continued to climb and reached a peak of 7.19% on July 5 and 8, 1996. For the period

8   leading up to the 1996 Presidential election, long-term Treasury bonds generally traded within

9   this range. After the election, interest rates moderated, returning to a level somewhat below the

10   previous trading range. Thereafter, in December 1996, interest rates returned to a range of 6.5%

11   to 7.0% which existed for much of 1996.

12   On March 25, 1997, the FOMC decided to tighten monetary conditions through a one-

13   quarter percentage point increase in the Fed Funds rate. This tightening increased the Fed Funds

14   rate to 5.5%. In making this move, the FOMC stated that it was concerned by persistent strength

15   of demand in the economy, which it feared would increase the risk of inflationary imbalances

16   that could eventually interfere with the long economic expansion.

17   In the fourth quarter of 1997, the yields on Treasury bonds began to decline rapidly in

18   response to an increase in demand for Treasury securities caused by a flight to safety triggered

19   by the currency and stock market crisis in Asia. Liquidity provided by the Treasury market

20   makes these bonds an attractive investment in times of crisis. This is because Treasury securities

21   encompass a very large market which provides ease of trading and carry a premium for safety.

22   During the fourth quarter of 1997, Treasury bond yields pierced the psychologically important

23   6% level for the first time since 1993.

1   Through the first half of 1998, the yields on long-term Treasury bonds fluctuated within a

2   range of about 5.6% to 6.1% reflecting their attractiveness and safety. In the third quarter of

3   1998, there was further deterioration of investor confidence in global financial markets. This

4   loss of confidence followed the moratorium (i.e., default) by Russia on its sovereign debt and

5   fears associated with problems in Latin America. While not significant to the global economy in

6   the aggregate, the August 17 default by Russia had a significant negative impact on investor

7   confidence, following earlier discontent surrounding the crisis in Asia.   These events

8   subsequently led to a general pull back of risk-taking as displayed by banks growing reluctance

9   to lend, worries of an expanding credit crunch, lower stock prices, and higher yields on bonds of

10   riskier companies. These events contributed to the failure of the hedge fund, Long-Term Capital

11   Management.

12   In response to these events, the FOMC cut the Fed Funds rate just prior to the mid-term

13   Congressional elections. The FOMC's action was based upon concerns over how increasing

14   weakness in foreign economies would affect the U.S. economy. As recently as July 1998, the

15   FOMC had been more concerned about fighting inflation than the state of the economy. The

16   initial rate cut was the first of three reductions by the FOMC. Thereafter, the yield on long-term

17   Treasury bonds reached a 30-year low of 4.70% on October 5, 1998. Long-term Treasury yields

18   below 5% had not been seen since 1967. Unlike the first rate cut that was widely anticipated, the

19   second rate reduction by the FOMC was a surprise to the markets. A third reduction in short-

20   term interest rates occurred in November 1998 when the FOMC reduced the Fed Funds rate to

21   4.75%.

22   All of these events prompted an increase in the prices for Treasury bonds which lead to

23   the low yields described above. Another factor that contributed to the decline in yields on long-

1   term Treasury bonds was a reduction in the supply of new Treasury issues coming to market due

2   to the Federal budget surplus -- the first in nearly 30 years. The dollar amount of Treasury bonds

3   being issued declined by 30% in two years thus resulting in higher prices and lower yields. In

4   addition, rumors of some struggling hedge funds unwinding their positions further added to the

5   gains in Treasury bond prices.

6   The financial crisis that spread from Asia to Russia and to Latin America pushed nervous

7   investors from stocks into Treasury bonds, thus increasing demand for bonds, just when supply

8   was shrinking. There was also a move from corporate bonds to Treasury bonds to take

9   advantage of appreciation in the Treasury market. This resulted in a certain amount of

10   exuberance for Treasury bond investments that formerly was reserved for the stock market.

11   Moreover, yields in the fourth quarter of 1998 became extremely volatile as shown by Treasury

12   yields that fell from 5.10% on September 29 to 4.70 percent on October 5, and thereafter

13   returned to 5.10% on October 13. A decline and rebound of 40 basis points in Treasury yields in

14   a two-week time frame is remarkable.

15   Beginning in mid-1999, the FOMC raised interest rates on six occasions reversing its

16   actions in the fall of 1998. On June 30, 1999, August 24, 1999, November 16, 1999, February 2,

17   2000, March 21, 2000, and May 16, 2000, the FOMC raised the Fed Funds rate to 6.50%. This

18   brought the Fed Funds rate to its highest level since 1991, and was 175 basis points higher than

19   the level that occurred at the height of the Asian currency and stock market crisis. At the time,

20   these actions were taken in response to more normally functioning financial markets, tight labor

21   markets, and a reversal of the monetary ease that was required earlier in response to the global

22   financial market turmoil.

23   As the year 2000 drew to a close, economic activity slowed and consumer confidence

1   began to weaken. In two steps at the beginning and at the end of January 2001, the FOMC

2   reduced the Fed Funds rate by one percentage point. These actions brought the Fed Funds rate to

3   5.50%. The FOMC described its actions as "a rapid and forceful response of monetary policy"

4   to eroding consumer and business confidence exemplified by weaker retail sales and business

5   spending on capital equipment and cut backs in manufacturing production. Subsequently, on

6   March 20, 2001, April 18, 2001, May 15, 2001, June 27, 2001, and August 21, 2001, the FOMC

7   lowered the Fed Funds in steps consisting of three 50 basis points decrements followed by two

8   25 basis points decrements. These actions took the Fed Funds rate to 3.50%. The FOMC

9   observed on August 21, 2001:

10   "Household demand has been sustained, but business profits and
11   capital spending continue to weaken and growth abroad is
12   slowing, weighing on the U.S. economy. The associated easing of
13   pressures on labor and product markets is expected to keep
14   inflation contained.
15
16   Although long-term prospects for productivity growth and the
17   economy remain favorable, the Committee continues to believe
18   that against the background of its long-run goals of price stability
19   and sustainable economic growth and of the information currently
20   available, the risks are weighted mainly toward conditions that
21   may generate economic weakness in the foreseeable future."
22

23   After the terrorist attack on September 11, 2001, the FOMC made two additional 50 basis points

24   reductions in the Fed Funds rate. The first reduction occurred on September 17, 2001 and

25   followed the four-day closure of the financial markets following the terrorist attacks. The second

26   reduction occurred at the October 2 meeting of the FOMC where it observed:

27   "The terrorist attacks have significantly heightened uncertainty in
28   an economy that was already weak. Business and household
29   spending as a consequence are being further damped.
30   Nonetheless, the long-term prospects for productivity growth and
31   the economy remain favorable and should become evident once

1   the unusual forces restraining demand abate."
2

3   Afterward, the FOMC reduced the Fed Funds rate by 50 basis points on November 6, 2001 and

4   by 25 basis points on December 11, 2001. In total, short-term interest rates were reduced by the

5   FOMC eleven (11) times during the year 2001. These actions cut the Fed Funds rate by 4.75%

6   and resulted in 1.75% for the Fed Funds rate.

7   In an attempt to deal with weakening fundamentals in the economy recovering from the

8   recession that began in March 2001, the FOMC provided a psychologically important one-half

9   percentage point reduction in the federal funds rate. The rate cut was twice as large as the

10   market expected, and brought the fed funds rate to 1.25% on November 6, 2002. The FOMC

11   stated that:

12   "The Committee continues to believe that an accommodative
13   stance of monetary policy, coupled with still-robust underlying
14   growth in productivity, is providing important ongoing support to
15   economic activity. However, incoming economic data have
16   tended to confirm that greater uncertainty, in part attributable to
17   heightened geopolitical risks, is currently inhibiting spending,
18   production, and employment. Inflation and inflation expectations
19   remain well contained.
20
21   In these circumstances, the Committee believes that today's
22   additional monetary easing should prove helpful as the economy
23   works its way through this current soft spot. With this action, the
24   Committee believes that, against the background of its long-run
25   goals of price stability and sustainable economic growth and
26   of the information currently available, the risks are balanced
27   with respect to the prospects for both goals in the foreseeable
28   future."
29

30   As 2003 unfolded, there was a continuing expectation of lower yields on Treasury

31   securities. In fact, the yield on ten-year Treasury notes reached a 45-year low near the end of the

32   second quarter of 2003. For long-term Treasury bonds, those yields culminated with a 4.24%

1   yield on June 13, 2003. Soon thereafter, the FOMC reduced the Fed Funds rate by 25 basis

2   points on June 25, 2003. In announcing its action, the FOMC stated:

3   "The Committee continues to believe that an accommodative
4   stance of monetary policy, coupled with still robust underlying
5   growth in productivity, is providing important ongoing support to
6   economic activity. Recent signs point to a firming in spending,
7   markedly improved financial conditions, and labor and product
8   markets that are stabilizing. The economy, nonetheless, has yet to
9   exhibit sustainable growth. With inflationary expectations
10   subdued, the Committee judged that a slightly more expansive
11   monetary policy would add further support for an economy which
12   it expects to improve over time."
13
14   Thereafter, intermediate and long-term Treasury yields moved marketedly higher. Higher yields

15   on long-term Treasury bonds, which exceeded 5.00% can be traced to: (i) the market's

16   disappointment that the Fed Funds rate was not reduced below 1.00%, (ii) an indication that the

17   Fed will not use unconventional methods for implementing monetary policy, (iii) growing

18   confidence in a strengthening economy, and (iv) a Federal budget deficit that is projected to be

19    $455 billion in 2003 (reported, subsequently, the actually deficit was $374 billion) and $475

20   billion in 2004 (revised subsequently, the estimated deficit is $500 billion in 2004). All these

21   factors significantly changed the sentiment in the bond market.

22   For the remainder of 2003, the FOMC continued with its balanced monetary policy,

23   thereby retaining the 1% Fed Funds rate. However, in 2004, the FOMC initiated a policy of

24   moving toward a more neutral Fed Funds rate (i.e., removing the bias of abnormal low rates).

25   On June 30, 2004, August 10, 2004, September 21, 2004, November 10, 2004, December 14,

26   2004, February 2, 2005, March 22, 2005, May 3, 2005, June 30, 2005, August 9, 2005,

27   September 20, 2005, November 1, 2005, December 13, 2005, January 31, 2006, March 28,

28   2006, May 10, 2006, and June 29, 2006, the FOMC increased the Fed Funds rate in seventeen

1   25 basis point increments. These policy actions are widely interpreted as part of the process of

2   moving toward a more neutral range for the Fed Funds rate. In its September 20, 2006 press

3   release, the FOMC stated:

4   "The moderation in economic growth appears to be continuing,
5   partly reflecting a cooling of the housing market.

6   Readings on core inflation have been elevated, and the high levels
7   of resource utilization and of the prices of energy and other
8   commodities have the potential to sustain inflation pressures.
9   However, inflation pressures seem likely to moderate over time,
10   reflecting reduced impetus from energy prices, contained inflation
11   expectations, and the cumulative effects of monetary policy actions
12   and other factors restraining aggregate demand.

13   Nonetheless, the Committee judges that some inflation risks
14   remain. The extent and timing of any additional firming that may
15   be needed to address these risks will depend on the evolution of the
16   outlook for both inflation and economic growth, as implied by
17   incoming information."

18   **Public Utility Bond Yields**

19   The Risk Premium analysis of the cost of equity is represented by the combination of a

20   firm's borrowing rate for long-term debt capital plus a premium that is required to reflect the

21   additional risk associated with the equity of a firm as explained in Appendix H. Due to the

22   senior nature of the long-term debt of a firm, its cost is lower than the cost of equity due to the

23   prior claim which lenders have on the earnings and assets of a corporation.

24   As a generalization, all interest rates track to varying degrees the benchmark yields

25   established by the market for Treasury securities. Public utility bond yields usually reflect the

26   underlying Treasury yield associated with a given maturity plus a spread to reflect the specific

27   credit quality of the issuing public utility. Market sentiment can also have an influence on the

28   spreads as described below. The spread in the yields on public utility bonds and Treasury bonds

1   varies with market conditions, as does the relative level of interest rates at varying maturities

2   shown by the yield curve.

3   Pages 1 and 2 of Schedule 8 provide the recent history of long-term public utility bond

4   yields for the rating categories of Aa, A and Baa (no yields are shown for Aaa rated public utility

5   bonds because this index has been discontinued). The top four rating categories of Aaa, Aa, A,

6   and Baa are known as "investment grades" and are generally regarded as eligible for bank

7   investments under commercial banking regulations. These investment grades are distinguished

8   from "junk" bonds which have ratings of Ba and below.

9   A relatively long history of the spread between the yields on long-term A-rated public

10   utility bonds and 20-year Treasury bonds is shown on page 3 of Schedule 8. There, it is shown

11   that those spreads were about the one percentage during for the years 1994 through 1997. With

12   the aversion to risk and flight to quality described earlier, a significant widening of the spread in

13   the yields between corporate (e.g., public utility) and Treasury bonds developed in 1998, after an

14   initial widening of the spread that began in the fourth quarter of 1997. The significant widening

15   of spreads in 1998 was unexpected by some technically savvy investors, as shown by the debacle

16   at the Long-Term Capital Management hedge fund. When Russia defaulted its debt on August

17   17, some investors had to cover short positions when Treasury prices spiked upward. Short

18   covering by investors that guessed wrong on the relationship between corporate and Treasury

19   bonds also contributed to run-up in Treasury bond prices by increasing the demand for them.

20   This helped to contribute to a widening of the spreads between corporate and Treasury bonds.

21   As shown on page 3 of Schedule 8, the spread in yields between A-rated public utility

22   bonds and 20-year Treasury bonds were about one percentage point prior to 1998, 1.32% in

23   1998, 1.42% in 1999, 2.01% in 2000, 2.13% in 2001, 1.94% in 2002, 1.62% in 2003, 1.12% in

1   2004, and 1.01% in 2005. As shown by the monthly data presented on pages 4 and 5 of

2   Schedule 8, the interest rate spread between the yields on 20-year Treasury bonds and A-rated

3   public utility bonds was 1.08 percentage points for the twelve-months ended September 2006.

4   For the six- and three-month periods ending September 2006, the yield spread was 1.09% and

5   1.10%, respectively.

6   **Risk-Free Rate of Return in the CAPM**

7   Regarding the risk-free rate of return (see Appendix I), pages 2 and 3 of Schedule 10

8   provide the yields on the broad spectrum of Treasury Notes and Bonds. Some practitioners of

9   the CAPM would advocate the use of short-term treasury yields (and some would argue for the

10 yields on 91-day Treasury Bills). Other advocates of the CAPM would advocate the use of

11 longer-term treasury yields as the best measure of a risk-free rate of return. As Ibbotson has

12 indicated:

13   The Cost of Capital in a Regulatory Environment. When discounting
14   cash flows projected over a long period, it is necessary to discount them
15   by a long-term cost of capital. Additionally, regulatory processes for
16   setting rates often specify or suggest that the desired rate of return for a
17   regulated firm is that which would allow the firm to attract and retain
18   debt and equity capital over the long term. Thus, the long-term cost of
19   capital is typically the appropriate cost of capital to use in regulated
20   ratesetting. (Stocks, Bonds, Bills and Inflation - 1992 Yearbook, pages
21   118-119)
22
23 As indicated above, long-term Treasury bond yields represent the correct measure of the risk-free

24 rate of return in the traditional CAPM. Very short term yields on Treasury bills should be

25 avoided for several reasons. First, rates should be set on the basis of financial conditions that

26 will exist during the effective period of the proposed rates. Second, 91-day Treasury bill yields

27 are more volatile than longer-term yields and are greatly influenced by FOMC monetary policy,

28 political, and economic situations. Moreover, Treasury bill yields have been shown to be

1   empirically inadequate for the CAPM. Some advocates of the theory would argue that the risk-

2   free rate of return in the CAPM should be derived from quality long-term corporate bonds.

RISK PREMIUM ANALYSIS

1

2   The cost of equity requires recognition of the risk premium required by common equities

3   over long-term corporate bond yields. In the case of senior capital, a company contracts for the

4   use of long-term debt capital at a stated coupon rate for a specific period of time and in the case

5   of preferred stock capital at a stated dividend rate, usually with provision for redemption through

6   sinking fund requirements. In the case of senior capital, the cost rate is known with a high

7   degree of certainty because the payment for use of this capital is a contractual obligation, and the

8   future schedule of payments is known. In essence, the investor-expected cost of senior capital is

9   equal to the realized return over the entire term of the issue, absent default.

10   The cost of equity, on the other hand, is not fixed, but rather varies with investor

11   perception of the risk associated with the common stock. Because no precise measurement

12   exists as to the cost of equity, informed judgment must be exercised through a study of various

13   market factors which motivate investors to purchase common stock. In the case of common

14   equity, the realized return rate may vary significantly from the expected cost rate due to the

15   uncertainty associated with earnings on common equity. This uncertainty highlights the added

16   risk of a common equity investment.

17   As one would expect from traditional risk and return relationships, the cost of equity is

18   affected by expected interest rates. As noted in Appendix G, yields on long-term corporate

19   bonds traditionally consist of a real rate of return without regard to inflation, an increment to

20   reflect investor perception of expected future inflation, the investment horizon shown by the term

21   of the issue until maturity, and the credit risk associated with each rating category.

1   The Risk Premium approach recognizes the required compensation for the more risky

2   common equity over the less risky secured debt position of a lender. The cost of equity stated in

3   terms of the familiar risk premium approach is:

4    $$k=i+RP$$

5   where, the cost of equity *("k")* is equal to the interest rate on long-term corporate debt *("i")*, plus

6   an equity risk premium *("RP")* which represents the additional compensation for the riskier

7   common equity.

8   **Equity Risk Premium**

9   The equity risk premium is determined as the difference in the rate of return on debt

10   capital and the rate of return on common equity. Because the common equity holder has only a

11   residual claim on earnings and assets, there is no assurance that achieved returns on common

12   equities will equal expected returns. This is quite different from returns on bonds, where the

13   investor realizes the expected return during the entire holding period, absent default. It is for this

14   reason that common equities are always more risky than senior debt securities. There are

15   investment strategies available to bond portfolio managers that immunize bond returns against

16   fluctuations in interest rates because bonds are redeemed through sinking funds or at maturity,

17   whereas no such redemption is mandated for public utility common equities.

18   It is well recognized that the expected return on more risky investments will exceed the

19   required yield on less risky investments. Neither the possibility of default on a bond nor the

20   maturity risk detracts from the risk analysis, because the common equity risk rate differential

21   (i.e., the investor-required risk premium) is always greater than the return components on a bond.

22   It should also be noted that the investment horizon is typically long-run for both corporate debt

1   and equity, and that the risk of default (i.e., corporate bankruptcy) is a concern to both debt and

2   equity investors. Thus, the required yield on a bond provides a benchmark or starting point with

3   which to track and measure the cost rate of common equity capital. There is no need to segment

4   the bond yield according to its components, because it is the total return demanded by investors

5   that is important for determining the risk rate differential for common equity. This is because the

6   complete bond yield provides the basis to determine the differential, and as such, consistency

7   requires that the computed differential must be applied to the complete bond yield when applying

8   the risk premium approach. To apply the risk rate differential to a partial bond yield would result

9   in a misspecification of the cost of equity because the computed differential was initially

10   determined by reference to the entire bond return.

11   The risk rate differential between the cost of equity and the yield on long-term corporate

12   bonds can be determined by reference to a comparison of holding period returns (here defined as

13   one year) computed over long time spans. This analysis assumes that over long periods of time

14   investors' expectations are on average consistent with rates of return actually achieved.

15   Accordingly, historical holding period returns must not be analyzed over an unduly short period

16   because near-term realized results may not have fulfilled investors' expectations. Moreover,

17   specific past period results may not be representative of investment fundamentals expected for

18   the future. This is especially apparent when the holding period returns include negative returns

19   which are not representative of either investor requirements of the past or investor expectations

20   for the future. The short-run phenomenon of unexpected returns (either positive or negative)

21   demonstrates that an unduly short historical period would not adequately support a risk premium

22   analysis. It is important to distinguish between investors' motivation to invest, which encompass

1   positive return expectations, and the knowledge that losses can occur. No rational investor

2   would forego payment for the use of capital, or expect loss of principal, as a basis for investing.

3   Investors will hold cash rather than invest with the expectation of a loss.

4   Within these constraints, page 1 of Schedule 9 provides the historical holding period

5   returns for the S&P Public Utility Index which has been independently computed and the

6   historical holding period returns for the S&P Composite Index which have been reported in

7   Stocks, Bonds, Bills and Inflation published by Ibbotson & Associates. The tabulation begins

8   with 1928 because January 1928 is the earliest monthly dividend yield for the S&P Public Utility

9   Index. I have considered all reliable data for this study to avoid the introduction of a particular

10   bias to the results. The measurement of the common equity return rate differential is based upon

11   actual capital market performance using realized results. As a consequence, the underlying data

12   for this risk premium approach can be analyzed with a high degree of precision. Informed

13   professional judgment is required only to interpret the results of this study, but not to quantify

14   the component variables.

15   The risk rate differentials for all equities, as measured by the S&P Composite, are

16   established by reference to long-term corporate bonds. For public utilities, the risk rate

17   differentials are computed with the S&P Public Utilities as compared with public utility bonds.

18   The measurement procedure used to identify the risk rate differentials consisted of

19   arithmetic means, geometric means, and medians for each series. Measures of the central

20   tendency of the results from the historical periods provide the best indication of representative

21   rates of return. In regulated ratesetting, the correct measure of the equity risk premium is the

22   arithmetic mean because a utility must expect to earn its cost of capital in each year in order to

1   provide investors with their long-term expectations. In other contexts, such as pension

2   determinations, compound rates of return, as shown by the geometric means, may be appropriate.

3   The median returns are also appropriate in ratesetting because they are a measure of the central

4   tendency of a single period rate of return. Median values have also been considered in this

5   analysis because they provide a return which divides the entire series of annual returns in half

6   and are representative of a return that symbolizes, in a meaningful way, the central tendency of

7   all annual returns contained within the analysis period. Medians are regularly included in many

8   investor-influencing publications.

9   As previously noted, the arithmetic mean provides the appropriate point estimate of the

10   risk premium. As further explained in Appendix I, the long-term cost of capital in rate cases

11   requires the use of the arithmetic means. To supplement my analysis, I have also used the rates

12   of return taken from the geometric mean and median for each series to provide the bounds of the

13   range to measure the risk rate differentials. This further analysis shows that when selecting the

14   midpoint from a range established with the geometric means and medians, the arithmetic mean is

15   indeed a reasonable measure for the long-term cost of capital. For the years 1928 through 2005,

16   the risk premiums for each class of equity are:

	S&P Composite	S&P Public Utilities
Arithmetic Mean	5.78%	5.27%
Geometric Mean	4.14%	3.18%
Median	8.94%	6.95%
Midpoint of Range	6.54%	5.07%
Average	6.16%	5.17%

1   The empirical evidence suggests that the common equity risk premium is higher for the S&P

2   Composite Index compared to the S&P Public Utilities.

3   If, however, specific historical periods were also analyzed in order to match more closely

4   historical fundamentals with current expectations, the results provided on page 2 of Schedule 9

5   should also be considered. One of these sub-periods included the 54-year period, 1952-2005.

6   These years follow the historic 1951 Treasury-Federal Reserve Accord which affected monetary

7   policy and the market for government securities.

8   A further investigation was undertaken to determine whether realignment has taken place

9   subsequent to the historic 1973 Arab Oil embargo and during the deregulation of the financial

10   markets. In each case, the public utility risk premiums were computed by using the arithmetic

11   mean, and the geometric means and medians to establish the range shown by those values. The

12   time periods covering the more recent periods 1974 through 2005 and 1979 through 2005 contain

13   events subsequent to the initial oil shock and the advent of monetarism as Fed policy,

14   respectively. For the 54-year, 32-year and 27-year periods, the public utility risk premiums were

15   6.05%, 5.19%, and 5.20% respectively, as shown by the average of the specific point-estimates

16   and the midpoint of the ranges provided on page 2 of Schedule 9.

1 **CAPITAL ASSET PRICING MODEL**

2   Modern portfolio theory provides a theoretical explanation of expected returns on

3 portfolios of securities. The Capital Asset Pricing Model ("CAPM") attempts to describe the

4 way prices of individual securities are determined in efficient markets where information is

5 freely available and is reflected instantaneously in security prices. The CAPM states that the

6 expected rate of return on a security is determined by a risk-free rate of return plus a risk

7 premium which is proportional to the non-diversifiable (or systematic) risk of a security.

8   The CAPM theory has several unique assumptions that are not common to most other

9 methods used to measure the cost of equity. As with other market-based approaches, the CAPM

10 is an expectational concept. There has been significant academic research conducted that found

11 that the empirical market line, based upon historical data, has a less steep slope and higher

12 intercept than the theoretical market line of the CAPM. For equities with a beta less than 1.0,

13 such as utility common stocks, the CAPM theoretical market line will underestimate the realistic

14 expectation of investors in comparison with the empirical market line which shows that the

15 CAPM may potentially misspecify investors' required return.

16   The CAPM considers changing market fundamentals in a portfolio context. The balance

17 of the investment risk, or that characterized as unsystematic, must be diversified. Some argue

18 that diversifiable (unsystematic) risk is unimportant to investors. But this contention is not

19 completely justified because the business and financial risk of an individual company, including

20 regulatory risk, are widely discussed within the investment community and therefore influence

21 investors in regulated firms. In addition, I note that the CAPM assumes that through portfolio

22 diversification, investors will minimize the effect of the unsystematic (diversifiable) component

1   of investment risk. Because it is not known whether the average investor holds a well-diversified

2   portfolio, the CAPM must also be used with other models of the cost of equity.

3   To apply the traditional CAPM theory, three inputs are required: the beta coefficient

4   *("β")*, a risk-free rate of return *("Rf")*, and a market premium *("Rm - Rf")*. The cost of equity

5   stated in terms of the CAPM is:

6                         $k = Rf + β (Rm - Rf)$

7   As previously indicated, it is important to recognize that the academic research has

8   shown that the security market line was flatter than that predicted by the CAPM theory and it had

9   a higher intercept than the risk-free rate. These tests indicated that for portfolios with betas less

10   than 1.0, the traditional CAPM would understate the return for such stocks. Likewise, for

11   portfolios with betas above 1.0, these companies had lower returns than indicated by the

12   traditional CAPM theory. Once again, CAPM assumes that through portfolio diversification

13   investors will minimize the effect of the unsystematic (diversifiable) component of investment

14   risk. Therefore, the CAPM must also be used with other models of the cost of equity, especially

15   when it is not known whether the average public utility investor holds a well-diversified

16   portfolio.

17   **Beta**

18   The beta coefficient is a statistical measure which attempts to identify the non-

19   diversifiable (systematic) risk of an individual security and measures the sensitivity of rates of

20   return on a particular security with general market movements. Under the CAPM theory, a

21   security that has a beta of 1.0 should theoretically provide a rate of return equal to the return rate

22   provided by the market. When employing stock price changes in the derivation of beta, a stock

1   with a beta of 1.0 should exhibit a movement in price which would track the movements in the

2   overall market prices of stocks. Hence, if a particular investment has a beta of 1.0, a one percent

3   increase in the return on the market will result, on average, in a one percent increase in the return

4   on the particular investment. An investment which has a beta less than 1.0 is considered to be

5   less risky than the market.

6   The beta coefficient $("\beta")$, the one input in the CAPM application which specifically

7   applies to an individual firm, is derived from a statistical application which regresses the returns

8   on an individual security (dependent variable) with the returns on the market as a whole

9   (independent variable). The beta coefficients for utility companies typically describe a small

10   proportion of the total investment risk because the coefficients of determination (R^2) are low.

11   Page 1 of Schedule 10 provides the betas published by Value Line. By way of

12   explanation, the Value Line beta coefficient is derived from a "straight regression" based upon

13   the percentage change in the weekly price of common stock and the percentage change weekly

14   of the New York Stock Exchange Composite average using a five-year period. The raw

15   historical beta is adjusted by Value Line for the measurement effect resulting in overestimates in

16   high beta stocks and underestimates in low beta stocks. Value Line then rounds its betas to the

17   nearest .05 increment. Value Line does not consider dividends in the computation of its betas.

Market Premium

19   The final element necessary to apply the CAPM is the market premium. The market

20   premium by definition is the rate of return on the total market less the risk-free rate of return

21   $("Rm - Rf")$. In this regard, the market premium in the CAPM has been calculated from the total

22   return on the market of equities using forecast and historical data. The future market return is

1   established with forecasts by Value Line using estimated dividend yields and capital appreciation

2   potential.

3   With regard to the forecast data, I have relied upon the Value Line forecasts of capital

4   appreciation and the dividend yield on the 1,700 stocks in the Value Line Survey. According to

5   the October 6, 2006, edition of The Value Line Investment Survey Summary and Index, (see

6   page 5 of Schedule 10) the total return on the universe of Value Line equities is:

7 8 9 10		Dividend Yield	+	Median Appreciation Potential	=	Median Total Return
11	As of October 6, 2006	1.7%	+	9.73%[1]	=	11.43%

12   The tabulation shown above provides the dividend yield and capital gains yield of the companies

13   followed by Value Line. Another measure of the total market return is provided by the DCF

14   return on the S&P 500 Composite index. As shown below, that return is 12.44%.

DCF Result for the S&P 500 Composite

D/P	(	1+.5g	)	+	g	=	k
1.80%	(	1.05275	)	+	10.55%	=	12.44%

where:	Price (P)	at	30-Sep-2006	=	1335.85
	Dividend (D)	for	2nd Qtr '06	=	6.02
	Dividend (D)		annualized	=	24.08
	Growth (g)		First Call EpS	=	10.55%

15   Using these indicators, the total market return is 11.94% (11.43% + 12.44% = 23.87% ÷ 2) using

16   both the Value Line and S&P derived returns. With the 11.94% forecast market return and the

17   5.25% risk-free rate of return, a 6.69% (11.94% - 5.25%) market premium would be indicated

18   using forecast market data.

---

[1]   The estimated median appreciation potential is forecast to be 45% for 3 to 5 years hence. The annual capital gains yield at the midpoint of the forecast period is 9.73% (i.e., $1.45^{.25} - 1$).

1   With regard to the historical data, I provided the rates of return from long-term historical

2 time periods that have been widely circulated among the investment and academic community

3 over the past several years, as shown on page 6 of Schedule 10. These data are published by

4 Ibbotson Associates in its Stocks, Bonds, Bills and Inflation ("SBBI"). From the data provided

5 on page 6 of Schedule 10, I calculate a market premium using the common stock arithmetic

6 mean returns of 12.3% less government bond arithmetic mean returns of 5.8%. For the period

7 1926-2005, the market premium was 6.5% (12.3% - 5.8%). I should note that the arithmetic

8 mean must be used in the CAPM because it is a single period model. It is further confirmed by

9 Ibbotson who has indicated:

10   *Arithmetic Versus Geometric Differences*
11   For use as the expected equity risk premium in the CAPM, the
12   *arithmetic* or *simple difference* of the *arithmetic* means of stock
13   market returns and riskless rates is the relevant number. This is
14   because the CAPM is an additive model where the cost of capital
15   is the sum of its parts. Therefore, the CAPM expected equity
16   risk premium must be derived by arithmetic, *not geometric*,
17   subtraction.
18
19   *Arithmetic Versus Geometric Means*
20   The expected equity risk premium should always be calculated
21   using the arithmetic mean. The arithmetic mean is the rate of
22   return which, when compounded over multiple periods, gives the
23   mean of the probability distribution of ending wealth values.
24   This makes the arithmetic mean return appropriate for
25   computing the cost of capital. The discount rate that equates
26   expected (mean) future values with the present value of an
27   investment is that investment's cost of capital. The logic of
28   using the discount rate as the cost of capital is reinforced by
29   noting that investors will discount their (mean) ending wealth
30   values from an investment back to the present using the
31   arithmetic mean, for the reason given above. They will therefore
32   require such an expected (mean) return prospectively (that is, in
33   the present looking toward the future) to commit their capital to
34   the investment. (Stocks, Bonds, Bills and Inflation - 1996
35   Yearbook, pages 153-154)

1   For the CAPM, a market premium of 6.60% (6.5% + 6.69% = 13.19% ÷ 2) would be

2 reasonable which is the average of the 6.5% using historical data and a market premium of

3 6.69% using forecasts.

1   <u>**COMPARABLE EARNINGS APPROACH**</u>

2   Value Line's analysis of the companies that it follows includes a wide range of financial

3   and market variables, including nine items that provide ratings for each company. From these

4   nine items, one category has been removed dealing with industry performance because, under the

5   approach employed, the particular business type is not significant. In addition, two categories

6   have been ignored that deal with estimates of current earnings and dividends because they are

7   not useful for comparative purposes. The remaining six categories provide relevant measures to

8   establish comparability. The definitions for each of the six criteria (from the Value Line

9   Investment Survey - Subscriber Guide) follow:

10   <div align="center">Timeliness Rank</div>
11
12   The rank for a stock's probable relative market performance in
13   the year ahead. Stocks ranked 1 (Highest) or 2 (Above Average)
14   are likely to outpace the year-ahead market. Those ranked 4
15   (Below Average) or 5 (Lowest) are not expected to outperform
16   most stocks over the next 12 months. Stocks ranked 3 (Average)
17   will probably advance or decline with the market in the year
18   ahead. Investors should try to limit purchases to stocks ranked 1
19   (Highest) or 2 (Above Average) for Timeliness.
20
21   <div align="center">Safety Rank</div>
22
23   A measure of potential risk associated with individual common
24   stocks rather than large diversified portfolios (for which Beta is
25   good risk measure). Safety is based on the stability of price,
26   which includes sensitivity to the market (see Beta) as well as the
27   stock's inherent volatility, adjusted for trend and other factors
28   including company size, the penetration of its markets, product
29   market volatility, the degree of financial leverage, the earnings
30   quality, and the overall condition of the balance sheet. Safety
31   Ranks range from 1 (Highest) to 5 (Lowest). Conservative
32   investors should try to limit purchases to equities ranked 1
33   (Highest) or 2 (Above Average) for Safety.

Financial Strength

The financial strength of each of the more than 1,600 companies in the VS II data base is rated relative to all the others. The ratings range from A++ to C in nine steps. (For screening purposes, think of an A rating as "greater than" a B). Companies that have the best relative financial strength are given an A++ rating, indicating an ability to weather hard times better than the vast majority of other companies. Those who don't quite merit the top rating are given an A+ grade, and so on. A rating as low as C++ is considered satisfactory. A rating of C+ is well below average, and C is reserved for companies with very serious financial problems. The ratings are based upon a computer analysis of a number of key variables that determine (a) financial leverage, (b) business risk, and (c) company size, plus the judgment of Value Line's analysts and senior editors regarding factors that cannot be quantified across-the-board for companies. The primary variables that are indexed and studied include equity coverage of debt, equity coverage of intangibles, "quick ratio", accounting methods, variability of return, fixed charge coverage, stock price stability, and company size.

Price Stability Index

An index based upon a ranking of the weekly percent changes in the price of the stock over the last five years. The lower the standard deviation of the changes, the more stable the stock. Stocks ranking in the top 5% (lowest standard deviations) carry a Price Stability Index of 100; the next 5%, 95; and so on down to 5. One standard deviation is the range around the average weekly percent change in the price that encompasses about two thirds of all the weekly percent change figures over the last five years. When the range is wide, the standard deviation is high and the stock's Price Stability Index is low.

Beta

A measure of the sensitivity of the stock's price to overall fluctuations in the New York Stock Exchange Composite Average. A Beta of 1.50 indicates that a stock tends to rise (or fall) 50% more than the New York Stock Exchange Composite Average. Use Beta to measure the stock market risk inherent in any diversified portfolio of, say, 15 or more companies. Otherwise, use the Safety Rank, which measures total risk

inherent in an equity, including that portion attributable to market fluctuations. Beta is derived from a least squares regression analysis between weekly percent changes in the price of a stock and weekly percent changes in the NYSE Average over a period of five years. In the case of shorter price histories, a smaller time period is used, but two years is the minimum. The Betas are periodically adjusted for their long-term tendency to regress toward 1.00.

Technical Rank

A prediction of relative price movement, primarily over the next three to six months. It is a function of price action relative to all stocks followed by Value Line. Stocks ranked 1 (Highest) or 2 (Above Average) are likely to outpace the market. Those ranked 4 (Below Average) or 5 (Lowest) are not expected to outperform most stocks over the next six months. Stocks ranked 3 (Average) will probably advance or decline with the market. Investors should use the Technical and Timeliness Ranks as complements to one another.

GLOSSARY OF ACRONYMS AND DEFINED TERMS	
ACRONYM	**DEFINED TERM**
AFUDC	Allowance for Funds Used During Construction
β	Beta
b	represents the retention rate that consists of the fraction of earnings that are not paid out as dividends
b x r	Represents internal growth
CAA	Clean Air Act
CAPM	Capital Asset Pricing Model
CCR	Corporate Credit Rating
D	Debt ratio
DCF	Discounted Cash Flow
d	Dividend rate on preferred stock
FERC	Federal Energy Regulatory Commission
FOMC	Federal Open Market Committee
g	Growth rate
GDP	Gross Domestic Product
IGF	Internally Generated Funds
LT	Long Term
M&A	Merger and acquisition
MLP	Master Limited Partnerships
P-E	Price earnings
P	Preferred stock
PUHC	Public Utility Holding Company
r	represents the expected rate of return on common equity
Rf	Risk-free rate of return
Rm	Market risk premium

GLOSSARY OF ACRONYMS AND DEFINED TERMS	
ACRONYM	**DEFINED TERM**
RP	Risk Premium
s	Represents the new common shares expected to be issued by a firm
s x v	Represents external growth
S&P	Standard & Poor's
v	represents the value that accrues to existing shareholders from selling stock at a price different from book value
